Radiocarbon in atmospheric $\text{CO}_2$ has successfully proven to be a very powerful tracer for carbon cycle studies and for quantifying $\text{CO}_2$ originating from the combustion of fossil fuels. The European research infrastructure ICOS (ICOS-RI.eu) has thus selected $^{14}\text{CO}_2$ as one of the key-species to be sampled at all atmospheric ICOS class 1 stations and to be analysed at the ICOS Central Radiocarbon Laboratory. ICOS follows a two-pronged sampling strategy for $^{14}\text{CO}_2$. On the one hand, flask samples will be collected during predefined meteorological conditions; on the other hand continuous, two-weekly integrated samples will be collected to estimate long-term trends of fossil fuel $\text{CO}_2$ at the sites.

We present the first results of ICOS integrated $^{14}\text{CO}_2$ samples from 10 European stations, starting in 2015. These measurements provide an overview of the current $^{14}\text{CO}_2$ levels at predominantly background stations and illustrate the influence from regional fossil fuel sources at individual stations.
